The theoretically optimal adsorption locations in hydroxyl (OH)-decorated metal-organic frameworks show that the captured carbon dioxide (CO₂) molecules interact with the *cis*-μ₂-OH groups in an end-on mode, which shows a moderate to weak hydrogen bond. The experimental isotherms and ideal adsorption solution theory (IAST) calculations show the high selectivity of CO₂ for nitrogen at 273, 283 and 295 K and 1.0 bar for three types of OH-appended isostructures.

The efficient capture and conversion of carbon dioxide (CO₂) is of great importance in realizing a carbon-neutral energy cycle and low-carbon society.¹ Over a long period of time, humans have become heavily reliant on fossil fuels in agriculture and industry, which is widely believed to present the major source for CO₂ emissions, thus leading to the rise of temperatures across the planet, from which a new kind of increasingly serious threat: global warming, may eventually have to be faced.² Although several developments of techniques for the capture of CO₂ have been developed, for example, effective and efficient CO₂ adsorption in alkylamine solutions, there are still a series of issues related to cost performance, storage, transportation, and safety with this.³ Therefore, the strong driving force has long been to use alternative high performance strategies to efficiently remove CO₂.

Currently, microporous metal-organic frameworks (MOFs), a subclass of crystalline hybrid polymers constructed from metallic cations/clusters and organic ligands, are

emerging as one of the most promising candidates for CO₂ capture because of their tunable structure, diverse topology, different chemical compositions of the micropores as well as the extra large specific surface area.⁴ Within the field of small molecule adsorption, a large amount of research has been focused on the mutual interaction mechanism between the MOF framework and the entrapped small molecule guests, especially for non-polar linear CO₂ molecule, thus discovering new functional materials with better performance. Recently, the group of Ibarra has demonstrated that alcohol confinement within a previously reported water-stable **InOF-1**,⁵ built from octahedral indium(III) hydroxide-biphenyltetracarboxylic acid [In₂(OH)₂(BPTC)] chain extended by BPTC ligands, can significantly promote CO₂ capture capacity with an approximately 3.6-fold increase of performance (from 3.8 to 13.7 mmol g⁻¹) at only 1.0 bar and 30 °C.⁶ In this case, more suitable narrow pore sizes which can effectively accommodate the small guest molecules and thus provide a

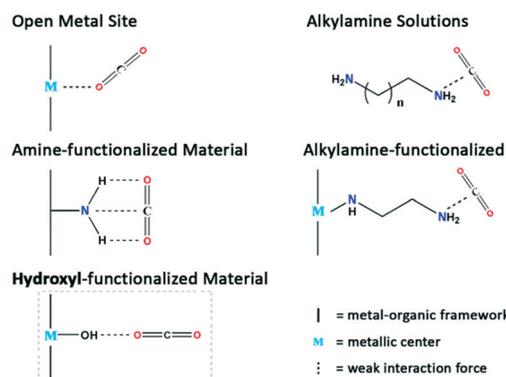

Fig. 1 CO₂ binding interactions in various MOF materials with different functional groups. In an OMS system, the CO₂ molecule uses its central carbon to connect to the MOF metallic center. The alkylamine solution, NH₂-functionalized, and alkylamine-functionalized MOF generally capture CO₂ molecules through a side-on mode, whereas in the OH-functionalized system, the CO₂ molecule attacks the OH group through an end-on mode.

strong overlapping potential have also been confirmed to enhance the CO₂ capacity as well as the sorption affinity.⁶ In this respect, it is also necessary to predict and visualize the CO₂ positions in the hydroxyl (OH)-decorated pore environment within the MOF materials using theoretical calculations and experimental tests.

It has been learned that high capacity storage in MOF materials can be achieved by the introduction of open metal sites (OMS),^{7a-c} where there exists a strong CO₂ binding strength which forms the Mⁿ⁺⋯C(=O)₂ bond because of the direct interaction between CO₂ and the coordinately unsaturated metal centers, causing irreversible physisorption and permanent loss of OMS activity. Fig. 1 shows that traditional alkylamine solutions, alkylamine-appended as well as polar amine-/sulfonate-/ketone-appended MOF materials^{7d-h} can be extensively utilized for the storage and separation of CO₂, but few examples are available showing that OH-functionalized MOF materials can effectively remove CO₂ because of the limited structural stability of the crystal compounds. In this paper, the optimization of CO₂ molecule sites in the InOF-1 framework using density functional theory (DFT) calculations, and a CO₂ adsorption behaviour comparison with an aluminium-/gallium-(Al/Ga)-based isostructural framework (AlOF-1 and GaOF-1, respectively), is reported, which confirms that all the OH-appended materials possess high CO₂

capacity and selectivity towards nitrogen (N₂) at 273 K, 283 K, and 295 K. Furthermore, it was found that AlOF-1 outperforms in CO₂ uptake because of the large binding energy used to structurally form AlOF-1·4CO₂. More importantly, a high selectivity of CO₂/N₂ at 273–295 K and 1.0 bar, and a large heat of CO₂ adsorption can be achieved at zero coverage (20.37 kJ mol⁻¹ for AlOF-1, 18.31 kJ mol⁻¹ for GaOF-1 and 11.98 kJ mol⁻¹ for InOF-1).

The pristine InOF-1 and ethanol (EtOH)-impregnated InOF-1 (InOF-1-EtOH) simultaneously exhibit an outstanding CO₂ capacity under the same conditions.⁶ Therefore, it is of great importance to understand the in-depth mechanism for the binding formation of small molecules and their hosts using direct visualization of the interaction between the CO₂ molecules and the InOF-1 framework. In this paper, the adsorption of CO₂ in one water-stable tetracarboxylate-based framework with an In(III) metal cation, [InOF-1, Fig. 2a and b and S2 (ESI†)] is mainly predicted and explained using DFT calculations. Meanwhile, the electron and energy properties of InOF-1 were calculated using a combination of DFT and plane-wave pseudopotential methods as implemented in the Vienna *Ab initio* Simulation Package (VASP) code.⁸ Calculations were performed under the Perdew–Burke–Ernzerhof (PBE) approximation⁹ for exchange and correlation with a plane-wave cutoff energy of 380 eV. The optimized unit cell

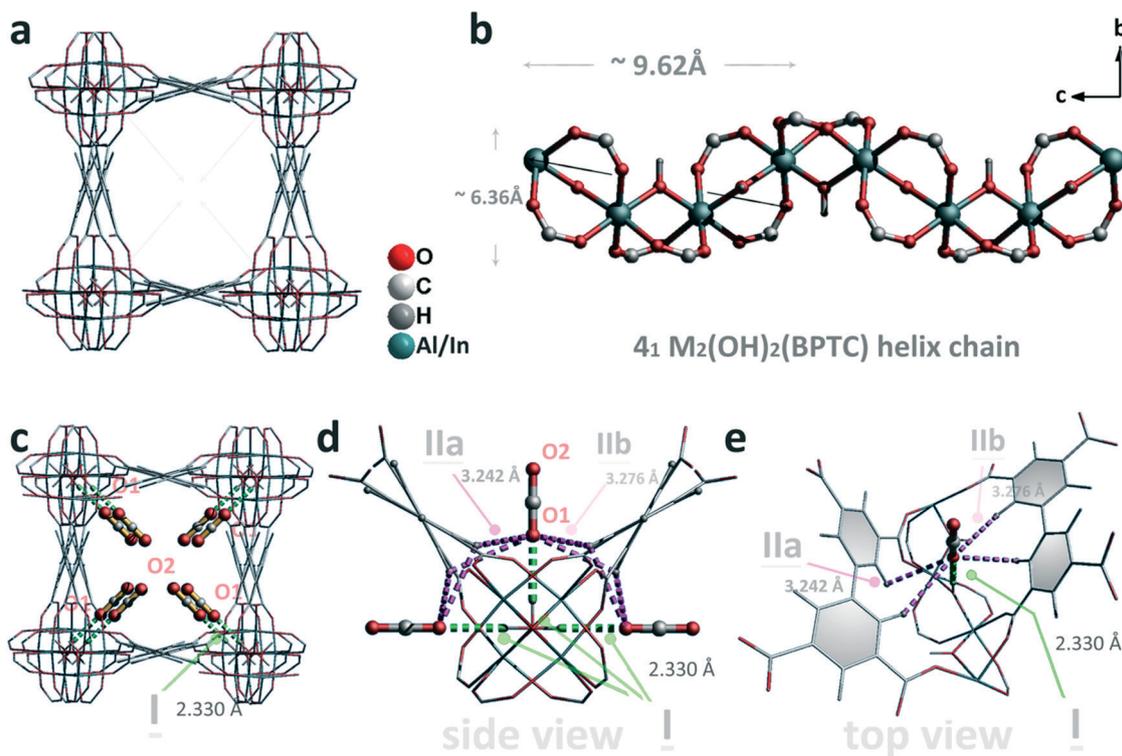

Fig. 2 Theoretically optimized CO₂ positions in the tetragonal channels of two isostructural M-BPTC frameworks. (a) View of the 3-dimensional structure with a square channel. The *cis*- μ_2 -OH groups protrude into the center of the channel from four directions. (b) View of the corner sharing octahedral [M₂(OH)₂(BPTC)] chain along the *a* axis. The different sizes of the 4₁ chain are highlighted. (c) View of the structure of M-BPTC-4CO₂ obtained using a combination of DFT and plane-wave pseudopotential methods as implemented in the VASP software. The adsorbed CO₂ molecules in the channel are highlighted by the use of the ball-and-stick mode. The interactions between CO₂ molecules and μ_2 -OH groups are highlighted in green. (d and e) Detailed views of the roles of the –OH and –CH groups in binding CO₂ molecules in a pocket-like cavity.

used has 72 and 84 atoms for the bare and four CO₂ molecules loaded materials (**InOF-1-4CO₂**, where each μ₂-OH group only connects to one CO₂ molecule), respectively. The wave functions were sampled according to the Monkhorst-Pack scheme with a *k*-point with mesh spacing of ~0.05 Å⁻¹.

As well as the **InOF-1** material, two other isostructural host **AlOF-1** and **GaOF-1** were also prepared,^{7d-f} and these possess a hydroxyl-functionalized 4₁ M₂(OH₂)(BPTC) helix chain (M = Al or Ga), whose sizes are ~6.36 × 9.62 Å² (Fig. 2b). DFT calculations were used to refine the crystal structure for the optimized **InOF-1-4CO₂** structures, and this shows that these adsorbed CO₂ molecules interact with the *cis*-μ₂-OH groups in an end-on mode (Fig. 2c). The O...H distance (*d_i*) between the entrapped CO₂ molecule and the hydroxyl group (H_{OH}) is 2.330 Å which indicates a relatively moderate to weak hydrogen bond (Table 1). The optimized C–O bond lengths in CO₂ were 1.179 Å (hydrogen bonded end, C–O1) and 1.173 Å (free end, C–O2), and the ∠OCO bond angle was absolutely linear and had a value of 180°. For the coordination environment of each captured CO₂ molecule, the hydrogen bonded O1 atom was also bolstered together by weak cooperative supramolecular interactions between the O1 atom and H atoms from biphenyl C–H groups (H_{CH}, O...H = 3.242 Å and 3.276 Å for *d_{Iia}* and *d_{Iib}*, respectively, and each occurs twice, Fig. 2d). In this context, the *d_{Iia}* and *d_{Iib}* distances in the **InOF-1-4CO₂** and **GaOF-1-4CO₂** structure (*d_{Iib}* = 3.202 Å) are slightly larger than that of the **AlOF-1-4CO₂** structure (*d_{Iia}* = 3.124 Å, *d_{Iib}* = 3.197 Å, see Table 1), which obviously indicates more strong interactions between the main MOF framework and the captured CO₂ molecules in the **AlOF-1** parent. A top view of the adsorbed CO₂ molecule in the OH-functionalized in-based chain, a total of 5 H atoms (4 H_{CH} atoms and 1 H_{OH} atom) attract cooperatively with the O1 charge centres of the captured CO₂ molecules in the tetragonal channel through the combination of the moderate to weak hydrogen bonds and the supramolecular interactions (Fig. 2e). As shown in Fig. 2c–e, the modest hydrogen bond between the O1 atom and the H_{OH} atom from the M–OH moiety is highlighted in green, and the weak cooperative hydrogen-bond interactions between O1 and H_{CH} H(dp) from the C–H groups are highlighted in pink for clarity and comparison.

However, in order to reveal the theory of the adsorption of CO₂ in these three types of isostructures, the binding energy

(Δ*E*), zero point energy correction (ZPEC), thermal energy correction (TEC) and binding enthalpy (Δ*H*) of **AlOF-1-4CO₂**, **GaOF-1-4CO₂** and **InOF-1-4CO₂** were calculated.

The Δ*E* of CO₂ is evaluated using the following equation:

$$\Delta E = -E_{\text{MOF-4CO}_2} + E_{\text{MOF}} + 4E_{\text{CO}_2} \quad (1)$$

in which *E_{MOF-4CO₂}* is the total energy of the framework and the adsorbed CO₂ molecule, *E_{MOF}* and *E_{CO₂}* are the energies of the framework and the CO₂ molecule, respectively.

The ZPEC for a system is then calculated as:¹⁰

$$\text{ZPEC} = \text{ZPE}_{\text{MOF-4CO}_2} - \text{ZPE}_{\text{MOF}} - 4\text{ZPE}_{\text{CO}_2} \quad (2)$$

where MOF and CO₂ are systems that are considered in isolation and then in combination as MOF-4CO₂ to determine the change in ZPE that results from the systems being placed in the presence of one another.

Similar to ZPEC, TEC is also *t* calculated as follows:¹⁰

$$\text{TEC} = \text{TE}_{\text{MOF-4CO}_2}(T) - \text{TE}_{\text{MOF}}(T) - 4\text{TE}_{\text{CO}_2}(T) \quad (3)$$

where MOF, CO₂ and MOF + CO₂ are as stated previously.

The binding enthalpies at a given temperature are calculated as:¹⁰

$$-\Delta H(T) = H(T)_{\text{MOF-4CO}_2} - H(T)_{\text{MOF}} - 4H(T)_{\text{CO}_2} \quad (4)$$

where *H(T)_{MOF}*, *H(T)_{CO₂}*, and *H(T)_{MOF-4CO₂}* are the enthalpy of the bare MOF without the guest molecule, the enthalpy of the molecule in the gas phase, and the enthalpy of the MOF with the molecule adsorbed, respectively, all at temperature, *T*. A positive Δ*H(T)* corresponds to an exothermic adsorption.

The previously described calculated energies are summarized in Table 1. In this table, the larger Δ*E* and Δ*H* represent stronger binding. Larger ZPEC and TEC values represent greater correction, that is to say, **AlOF-1** (ZPEC = 9.910 kJ mol⁻¹, TEC = 35.827 kJ mol⁻¹) tends to possess greater correction with CO₂ than both **GaOF-1** and **InOF-1**. A stronger binding generates greater confinement and a steeper potential well, and thus yields a larger ZPEC but less thermal motion inside the well.¹⁰ This means that **AlOF-1-4CO₂** is easier to form than **GaOF-1-4CO₂** or **InOF-1-4CO₂**. Consequently, agreement is achieved between the previously reported results and this data.

To compare the previously calculated results with experimental CO₂ adsorption tests, **InOF-1**, **AlOF-1** as well as **GaOF-1** materials were synthesized according to previous methods reported in the literature for better comparison.^{5a,7d,f,11} In order to confirm the permanent porosity, the N₂ isotherms at 77 K were first determined prior to the CO₂ sorption test. The desolvated **InOF-1** and **GaOF-1** samples showed totally reversible type-I isotherms with the maximum uptake value of 270.9/131.1 m³ g⁻¹ at 1.0 bar and 77 K which corresponds to a Brunauer–Emmett–Teller (BET) and Langmuir surface area of 1065/1093 m² g⁻¹ and 517/570 m² g⁻¹, respectively. In contrast, the activated **AlOF-1** powder exhibited barely any N₂ sorption

Table 1 The specific bond is listed (in Å units) and the binding energy, zero point energy, thermal energy and binding enthalpy at 300 K (in kJ mol⁻¹)

Δ <i>H</i> (kJ mol ⁻¹)	78.341	65.568	60.215

capacity at 77 K, with a maximum value of only $13.4 \text{ cm}^3 \text{ g}^{-1}$ at 1.0 bar and 77 K (Fig. 3a). Despite the microporous window size and the rigid framework for AIOF-1, it was surprising that the low N_2 diffusion into the voids can be observed at 77 K. It was assumed this behaviour might be derived from a strong interaction between the nitrogen molecules and the narrow pore windows by the considerable quadrupole interactions with the electrostatic field gradients near the surface, which subsequently prohibit other molecules from penetrating into the voids,¹² because the AIOF-1 framework possesses only open 1-dimensional channels along the *c*-axis.

Most importantly, the fascinating internal OH-suspended tetragonal tubes inevitably prompt the further investigation of the practical CO_2 sorption capacity. Single component low-pressure gas sorption isotherms for the three types of desolvated samples toward CO_2 at 273 K, 283 K, and 295 K were collected using a volumetric measurement method and the results obtained are presented in Fig. 4a and Fig. S9–11 (ESI[†]). Compared to its very low sorption for N_2 , the CO_2 isotherms of AIOF-1 at the specific temperatures (273–295 K) show extremely high sorption capacities, with the saturated value of $155.5 \text{ cm}^3 \text{ g}^{-1}$ (6.94 mmol g^{-1} , 305.4 mg g^{-1}) at 273 K and 1.0 bar. Meanwhile, it was also found that the CO_2 adsorption curve quickly reached the value of $42.6 \text{ cm}^3 \text{ g}^{-1}$ (1.90 mmol g^{-1} , 83.7 mg g^{-1}) at 0.15 bar, which is lower than the equivalent partial pressure in flue gas (Fig. 4a). Obviously, this capacity surpasses the InOF-1 adsorption value of $39.1 \text{ cm}^3 \text{ g}^{-1}$ (1.75 mmol g^{-1} , 76.8 mg g^{-1}) at 273 K and 0.15 bar and $140.1 \text{ cm}^3 \text{ g}^{-1}$ (6.25 mmol g^{-1} , 275.2 mg g^{-1}) at 273 K and 1.0 bar. Similar trends can also be found in the uptake of CO_2 at 1.0 bar and 283 K and 295 K, where the AIOF-1 shows a good performance with $118.6 \text{ cm}^3 \text{ g}^{-1}$ and $86.7 \text{ cm}^3 \text{ g}^{-1}$, respectively, whereas the InOF-1 exhibits a lower capability towards CO_2 with $109.5 \text{ cm}^3 \text{ g}^{-1}$ at 283 K and $83.9 \text{ cm}^3 \text{ g}^{-1}$ at 295 K. Furthermore, in terms of CO_2 storage, the Ga-based material shows the lowest capability of 90.3 , 71.6 and $56.6 \text{ cm}^3 \text{ g}^{-1}$ [Fig. 4b and S15 (ESI[†])]. In this case, it was speculated that there exists a strong interaction between the solvent molecules and the GaOF-1

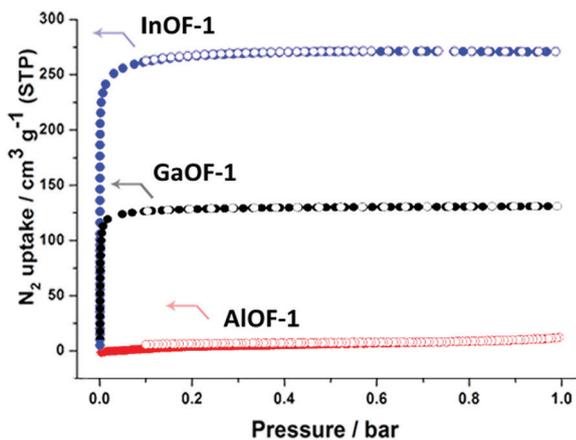

Fig. 3 N_2 adsorption/desorption isotherms at 77 K for AIOF-1, GaOF-1 and InOF-1. ● adsorption, ○ desorption.

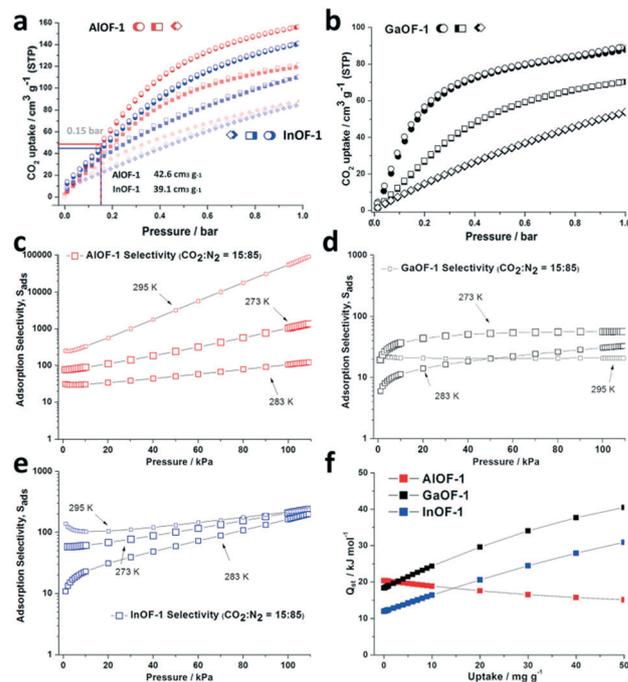

Fig. 4 (a) and (b) Experimental CO_2 sorption isotherms at 273 K (● adsorption, ○ desorption), 283 K (■ adsorption, □ desorption) and 295 K (◆ adsorption, ◇ desorption). (c)–(e) The selectivity between CO_2 and N_2 at three different temperatures for AIOF-1, GaOF-1 and InOF-1. (f) The adsorption heat (Q_{st}) of CO_2 for the three types of isostructural M-BPTC materials fitted using the virial method.

framework, thus leading to the incomplete desolvation and inadequate utilization of the expected pore volume. However, it should be noted that the CO_2 capacity of AIOF-1 and InOF-1 materials gradually gets closer when the temperature is elevated from 273 K to 295 K (Fig. 4a), which means that the active CO_2 spacing in AIOF-1 is lost faster than that in InOF-1. However, a large amount of CO_2 is still retained under these different temperatures, especially for the Al-based framework, which indicates the excellent retention of the microporous nature before and after the desolvation treatment and gas sorption, as shown in Fig. S6 and S7 (ESI[†]).

Finally, the IAST prediction based upon the experimental CO_2 and N_2 isotherms are clearly presented in Fig. 4b. The adsorption selectivity is defined as $S_{ij} = (q_1/q_2)/(p_1/p_2)$, in which q_i is the amount of *i* adsorbed and p_i is the partial pressure of *i* in the mixture. At 1.0 bar, the calculated CO_2/N_2 selectivities for AIOF-1 are more variable: 1078.8 and 108.4 at 273 K and 283 K from gas-phase mixtures in a 15:85 molar ratio, whereas at 295 K, it reaches an excessive amount of 58 571.6 because of the very low capacity of N_2 at 1.0 bar. Compared to that of the Al-based material, the theoretically calculated CO_2/N_2 selectivity values for GaOF-1 and InOF-1 are more reasonable and trustworthy, where they are $56.7/212.6$, $31.1/168.1$ and $20.8/219.6$ at 273, 283 and 295 K, respectively, [Fig. 4c–e, S20–22 (ESI[†])]. More interestingly, the heat of CO_2 adsorption at zero coverage is calculated to be $20.37 \text{ kJ mol}^{-1}$ (AIOF-1), $18.31 \text{ kJ mol}^{-1}$ (GaOF-1), and $11.98 \text{ kJ mol}^{-1}$ (InOF-1) based on the CO_2

isotherms at 283 K and 295 K, which indicates a more reasonable order for this series of M-BPTC structures despite the deficient performance for GaOF-1 in the CO₂ sorption analysis (Fig. 4f). These calculations and observation indicate that all the OH-functionalized materials are promising candidates for practical CO₂ capture and conversion applications.

In summary, with a combination of theoretical calculations and experimental tests, the role of group A(III) metals in three types of OH-appended M-BPTC MOFs, including AlOF-1, GaOF-1 and InOF-1 were thoroughly compared. In this series, it was found that the CO₂ binding to the *cis*- μ_2 -OH groups is in an end-on mode and this is further supported by H-bonding with adjacent biphenyl rings. The experiments and IAST results demonstrate that the largest binding energy and adsorption heat exist in the Al(III)-OH...C(=O)₂ system which could be empirically predicted by the atomic mass of the cations in the isostructural frameworks. This research provides a useful guideline for the future development of versatile MOFs with functionalized groups.
